

# **Lab 1: Concurrency vs Parallelism**

**COE892 Rover and Mines**

**Klajdi Moglica**

**Note: Registered with AAS for extra time.**

## Introduction:

This lab focuses on navigating rovers through a 2D minefield and disarming mines using hashing techniques. It involves fetching movement commands, simulating traversal, and implementing mine disarming with both sequential and parallel execution to compare performance and efficiency.

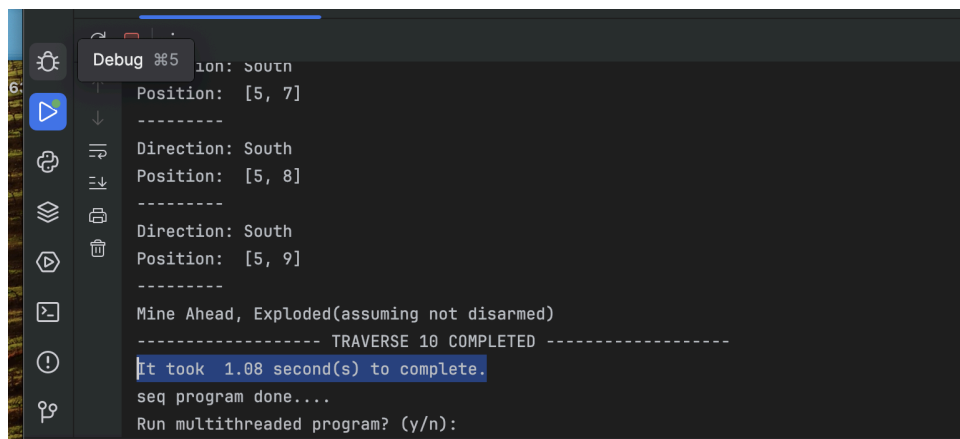

## Implementation description:

Part 1 – Simulates moving rovers across a 2D grid (map) and tracks their paths. Each rover executes a series of movement instructions fetched from an API, and the program writes the resulting paths to separate files (path\_1.txt, path\_2.txt, etc.). This functionality is implemented both sequentially and in parallel.

Part 2 – Load the minefield from mines.txt, fetches movement instructions from the fetched API, moves the rover through the minefield, handles mines by using hashing, executes everything first sequentially then in parallel.

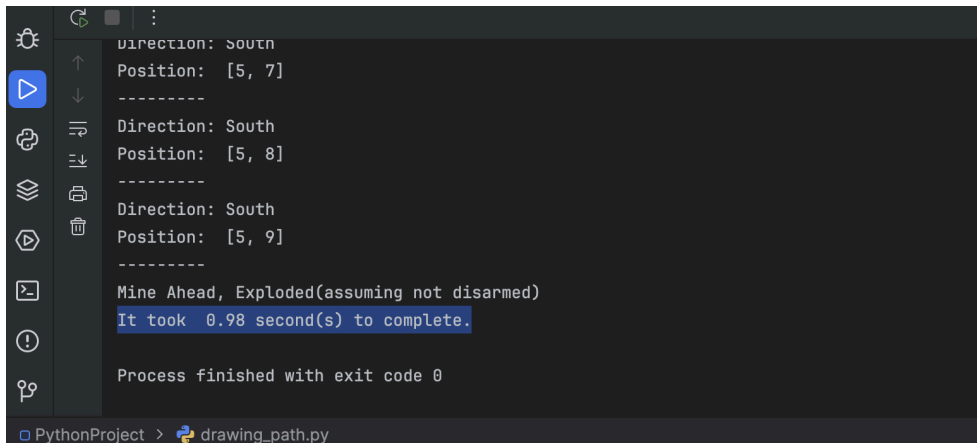

## Results section:

Part 1 – Drawing path:

```
Debug %5 10n: South
Position: [5, 7]
-----
Direction: South
Position: [5, 8]
-----
Direction: South
Position: [5, 9]
-----
Mine Ahead, Exploded(assuming not disarmed)
----- TRAVERSE 10 COMPLETED -----
It took 1.08 second(s) to complete.
seq program done...
Run multithreaded program? (y/n):
```

Total processing time: 1.08 seconds for the single threaded program.

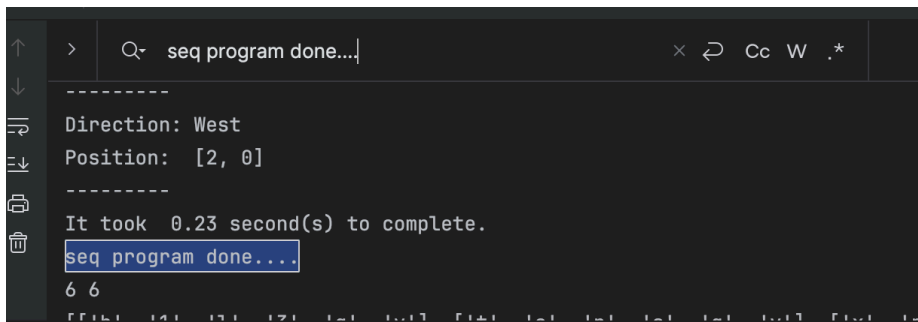

```
direction: South
Position: [5, 7]
-----
Direction: South
Position: [5, 8]
-----
Direction: South
Position: [5, 9]
-----
Mine Ahead, Exploded(assuming not disarmed)
It took 0.98 second(s) to complete.
Process finished with exit code 0
```

Total processing time: 0.98 seconds for the multithreaded program.

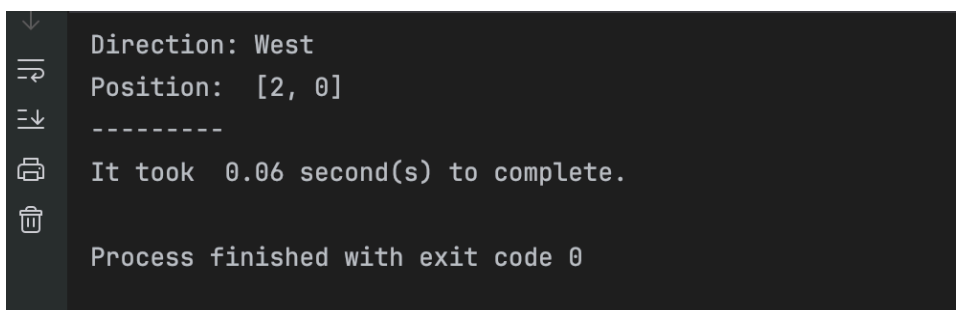

Difference of their computation times: The multithreaded program was 0.10 seconds quicker than the single threaded program.

## Part 2 – Digging Mines:

```
Direction: West
Position: [2, 0]
-----
It took 0.23 second(s) to complete.
seq program done....
6 6
```

Total processing time: 0.23 seconds for the single threaded program.

```
Direction: West
Position: [2, 0]
-----
It took 0.06 second(s) to complete.
Process finished with exit code 0
```

Total processing time: 0.06 seconds for the multithreaded program.

Difference of their computation times: The multithreaded program was 0.17 seconds quicker than the single threaded program. That's a significant improvement.

## **Conclusion:**

**The lab demonstrated effective rover navigation, mine disarming, and performance improvements through multithreading. Sequential and parallel approaches highlighted trade-offs between clarity and efficiency, providing hands-on experience with key programming concepts like file handling, API requests, and multithreading.**

I also wanted to mention something interesting I noticed. The third criterion of part 2 adds a computational bottleneck and simulates the real-world effort involved in validating or cracking cryptographic-like hashes. I noticed how long 6 leading zeros were taking, and I realized that finding a valid PIN is not trivial. This part of the lab demonstrated the use of brute-force techniques for solving complex problems.
